Report Overview

Intracranial embolic coils are medical devices used to treat cerebral aneurysms by filling and occluding the aneurysm sac. These coils are inserted into the aneurysm via a catheter threaded through the blood vessels, typically accessed through the femoral artery. Once positioned inside the aneurysm, the coils are deployed to create a dense meshwork that promotes blood clotting within the sac, effectively sealing it off from the rest of the circulatory system. This procedure, known as endovascular coiling, helps prevent the aneurysm from rupturing, thereby reducing the risk of hemorrhagic stroke. Intracranial embolic coils are a minimally invasive and highly effective treatment option for patients with cerebral aneurysms.
