Abstracts

Intravenous general anesthetics are a class of drugs used to induce and maintain anesthesia during surgical procedures. Administered directly into the bloodstream, these medications act quickly to produce a state of unconsciousness and analgesia, allowing for pain-free and immobile surgery. Common examples include propofol, which provides rapid onset and quick recovery, and thiopental, known for its ultra-short duration of action. These drugs work by depressing the central nervous system, specifically targeting neurotransmitter systems to suppress consciousness and sensory perception. The choice of anesthetic often depends on factors such as the type of surgery, patient health, and desired duration of effect.

The global Intravenous General Anesthetics Drug market size was estimated at USD 2806.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.60% during the forecast period.
