Report Overview:

In a healthy body, when the stores of iron are sufficient, the intestines reduce the absorption of this mineral from food and drink to prevent its levels from rising too high.

People with iron overload disorders absorb more iron than usual from food or supplements. The body cannot excrete the extra iron fast enough, so it continues to build up. The body stores it in organ tissue, mainly in the liver, as well as the heart and the pancreas.

There are several types of iron overload disorder. Hereditary hemochromatosis is a primary condition that has a genetic component. People can also have secondary hemochromatosis, which develops as a result of another disease or condition.

The rationale behind using Iron chelation therapy is removing the increased iron burden specifically labile cell iron (LCI) to minimize production of reactive oxygen species (ROS) thereby decreasing cellular and organ damage. Patients most likely to benefit from chelation therapy include those with low or intermediate-1 IPSS risk MDS who have a long-life expectancy and are anticipated to receive more than 20 red blood cell transfusions and/or whose serum ferritin level is >1000 µg/L. Chelation therapy efficacy can be monitored by monitoring trends and levels of serum ferritin.

The Global Iron Chelation Drug Market Size was estimated at USD 662.81 million in 2023 and is projected to reach USD 431.60 million by 2029, exhibiting a CAGR of -6.90% during the forecast period.
