Abstracts

Ladder filter is a device that realizes filtering function by constructing a one-port ladder structure. This filter usually uses surface acoustic wave (SAW) resonators or other types of resonant elements, arranged and coupled in a ladder structure to achieve a specific filtering effect. The core of ladder filter lies in its ladder structure, which makes the filter present unique characteristics in frequency response. The filter contains multiple resonant elements, which can be SAW resonators, LC resonant circuits or other types of resonant structures. The resonant elements are connected to each other by electrical coupling or magnetic coupling to form a complex filtering network. The working principle of ladder filter is based on the frequency selection characteristics of resonant elements. When the input signal passes through the filter, only the signal components that match the frequency of the resonant element can pass, while the signals of other frequencies are suppressed or attenuated. By adjusting the parameters and coupling methods of the resonant elements, filtering and selection of signals of different frequencies can be achieved.

The global Ladder Filter market size was estimated at USD 178.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.30% during the forecast period.
