Report Overview

Lateral Seismic Brackets are a type of structural support system used to enhance the seismic performance of buildings during earthquakes. These brackets consist of metal braces or supports that are strategically placed at the sides of structural elements, such as columns or walls, to provide added lateral strength and resistance to seismic forces. Lateral Seismic Brackets effectively redistribute and absorb the energy generated during an earthquake, minimizing structural damage and ensuring the safety of the building and its occupants. By reinforcing key structural components, these brackets help prevent collapse, reduce repair costs, and increase the overall seismic resilience of buildings in high-risk areas.
