Abstracts

A Mach-Zehnder Modulator (MZM) is an integrated optical device used to modulate light by varying its intensity through interference effects. It consists of an input waveguide that splits light into two arms, one or both of which incorporate an electro-optic material whose refractive index changes in response to an applied electric voltage. This phase shift alters the interference conditions when the light recombines, converting electrical signals into controlled optical output intensity. Widely employed in high-speed fiber-optic communication systems, MZMs are critical for encoding data onto laser carriers with minimal distortion, supporting applications in telecommunications, data centers, and optical sensing due to their high bandwidth, linearity, and compatibility with semiconductor fabrication processes.

The global Mach Zehnder Modulator market size was estimated at USD 1050.53 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 10.50% during the forecast period.
