Abstracts

Marine carbon dioxide removal refers to a series of technological pathways aimed at mitigating climate change by enhancing the ocean's capacity to absorb and store atmospheric carbon dioxide through human intervention. Its core lies in leveraging the ocean, the world's largest active carbon sink, and using physical, chemical, or biological methods to overcome the limitations of natural cycles and achieve active carbon removal and long-term storage. Key methods include increasing seawater alkalinity to enhance its chemical carbon sequestration capacity, using nutrients or artificial upwelling to stimulate phytoplankton growth and strengthen the biopump effect, conducting large-scale seaweed cultivation followed by seabed deposition, and directly performing deep-sea carbon dioxide sequestration. These technologies aim to synergistically mitigate ocean acidification, but all face key challenges such as ecological risks, monitoring and verification, and global governance, representing the forefront of current negative emission technology research. Currently, global exploration of marine carbon dioxide removal exhibits significant regional characteristics. North America (represented by the United States) and Europe lead in technological research and development, financial investment, and the number of startups, driving the technology from the laboratory to small-scale offshore trials. In the Asia-Pacific region, countries such as China and Japan are making rapid progress in related basic research and technology demonstrations, with Japan already conducting early-stage marine alkalization experiments. Notably, small island developing states and countries with vast exclusive economic zones (such as Norway and Canada), due to their close interdependence with the ocean, are highly cautious about the ecological risks of such technologies, emphasizing an international governance framework based on early warning principles. Globally, related activities remain highly concentrated along the coasts of developed countries with strong scientific research capabilities, and applications in areas such as the high seas are still largely unexplored due to complex

legal and ethical issues.

The global Marine Carbon Dioxide Removal market size was estimated at USD 713.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 14.00% during the forecast period.
