### Report Overview

In maskless photolithography system, the radiation that is used to expose a photosensitive emulsion (or photoresist) is not projected from, or transmitted through, a photomask. Instead, most commonly, the radiation is focused to a narrow beam which directly writes the image into the photoresist, one or more pixels at a time. A key advantage of maskless photolithography is the ability to change lithography patterns from one run to the next, without incurring the cost of generating a new photomask. This may prove useful for double patterning.

The global Maskless Lithography System market size was estimated at USD 313.20 million in 2023 and is projected to reach USD 570.98 million by 2032, exhibiting a CAGR of 6.90% during the forecast period.
