Report Overview

Mechanical debridement is a nonselective type of debridement, meaning that it will remove both devitalized tissue and debris as well as viable tissue. It is usually carried using mechanical force: wet-to-dry, pulsatile lavage, or wound irrigation.

It is indicated for both acute and chronic wounds with moderate to large amounts of necrotic tissue, regardless of the presence of an active infection.

The contraindications include, depending on the modality of mechanical debridement used, the presence of granulation tissue in a higher amount than the devitalized tissue, inability to control pain, patients with poor perfusion, and an intact eschar with no gross clinical evidence of an underlying infection.
