Report Overview

Membrane filtration is a method of separating particles from liquid solution or gas mixture. The semipermeable membrane acts as a barrier to retain larger particles while allowing smaller molecules to enter the permeate through the membrane. Membrane filtration can be used for a range of products with different viscosities, including high viscosity products that are difficult to process. The basic technology behind membrane filtration involves the use of semi permeable membranes to separate liquids into two different streams. The membrane surface is kept unobstructed by the force of the liquid flow moving parallel to the membrane surface. There are four levels of membrane filtration. These levels are (from maximum to minimum pore size): microfiltration, ultrafiltration, nanofiltration and reverse osmosis. Each level has an associated pore size range for the removal of contaminants of a specific size.
