Abstracts

Mesoporous silica microspheres are a kind of nanomaterials with special structure and properties. Mesoporous silica microspheres are mainly composed of silicon dioxide (SiO_2), which is a common inorganic material with excellent physical and chemical properties. Mesoporous silica microspheres have a highly ordered pore structure, uniform pore distribution, and controllable pore size, usually between 2 and 50 nanometers. Due to the presence of pores, mesoporous silica microspheres have a large specific surface area, which enables them to adsorb a large number of molecules and have excellent adsorption properties. Large pores are conducive to the diffusion and storage of molecules, so mesoporous silica microspheres have a large pore capacity, which improves their drug loading and other capabilities. The surface of silica contains many active hydroxyl groups ($-\text{OH}$), and different functional groups can be introduced through chemical modification to achieve selective adsorption or covalent binding of different compounds. In summary, mesoporous silica microspheres are a kind of nanomaterial with a highly ordered pore structure, high specific surface area and large pore capacity. Its unique physical and chemical properties make it have broad application prospects in the fields of drug delivery, catalyst carriers, adsorbents, sensors, etc.

The global Mesoporous Silica Microspheres market size was estimated at USD 1472.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.10% during the forecast period.
