Report Overview

Metachromatic leukodystrophy disease (MLD) is a deadly genetic condition caused by mutations in the ARSA gene that results in brain impairment and developmental retardation. In its most severe and prevalent forms, young children rapidly lose their capacity to walk, communicate, and interact with their surroundings, and the majority die before reaching puberty. Metachromatic leukodystrophy is characterized by sulfatide deposition in cells. This accumulating has a particular impact on nervous system cells that create myelin, a material that insulates and protects neurons. White matter is a tissue made composed of nerve cells coated with myelin. This damages the protective myelin sheathing the neurons, leading to gradual deterioration of the brain and nervous system functioning. This disease has three forms that are Late Infantile Form, Juvenile Form, and Adult Form. Pipeline products, which can only treat symptoms of the disease, are among the medical treatment. These products have the potential to prevent nerve damage, reduce the development of the illness, avoid complications, and provide pain relief.
