Abstracts

Metal bismuth nanomaterials represent a class of engineered materials characterized by their nanoscale dimensions (typically 1?100 nanometers) and composed primarily of bismuth, a heavy, brittle metal with distinctive properties including low toxicity, high electrical resistance, diamagnetism, and a high atomic number. These nanomaterials are synthesized through various methods such as solvothermal reduction, laser ablation, or electrochemical deposition, resulting in structures like nanoparticles, nanowires, nanosheets, or nanotubes, often with tailored surface chemistry, crystallinity, and morphology to enhance specific functional attributes such as catalytic activity, plasmonic behavior, or biocompatibility. Their unique physicochemical properties?including a small bandgap, strong near-infrared absorption, high surface-area-to-volume ratio, and favorable electronic structure?make them suitable for applications across diverse fields, from energy storage and conversion (e.g., in batteries and photocatalysis) to biomedical uses (e.g., in imaging, drug delivery, and photothermal therapy), as well as in environmental remediation and electronic devices.

The global Metal Bismuth Nanomaterials market size was estimated at USD 125.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 18.75% during the forecast period.
