### Report Overview

The cellulose polymer is a naturally occurring linear polymer made of repeating units of glucose. Single polymers are stacked together forming fibrils, and these fibrils stack together again to form the cellulose fiber structure that is present in nature. This makes for a very interesting supramolecular structure that consists of both crystalline and amorphous regions.

Microfibrillated cellulose (MFC) is obtained through a fibrillation process of cellulose fibers. Using mechanical shearing, the cellulose fibers are separated into a three dimensional network of microfibrils with a large surface area. The obtained fibrils are much smaller in diameter compared to the original fibers, and can form a network or a web-like structure as seen in the image below.

This report provides a deep insight into the global Microfibrillated Cellulose market covering all its essential aspects.
