Report Overview

Microtomes are instruments that are used for making extremely thin sections of a specimen for applications in pathology or histology. A microtome comprises a blade holding unit and clamped blade. It also consists of an object clamp and an advanced procedure for adjusting section thickness. The blade used is made of glass, special metal, or diamond depending on the sample type and the desired thickness. Cryostat refers to ultrafine deli-slicer placed in a freezer. They are rotary microtomes for slicing samples that have been frozen in liquid nitrogen. Reducing the temperature of this nitrogenous chamber raises the sample's hardness, which allows slicing the sample with very specific thickness. Microtome cryostat provides the most reliable method for obtaining permanent frozen sections of high quality.

With the increasing demand on laboratories to deliver test results in the quickest turnaround time (TAT), both microtomes and cryostats are now being utilized, depending on quality or reduced TAT is of optimum requirement. Automated stainers, on the other hand, are very useful in such cases by allowing system automation for situ hybridization (ISH) and immunohistochemistry (IHC) in histopathology. The global market for microtomes, cryostats, and automated stainers will witness immense growth in the near future.
