Report Overview:

Microturbines are small gas turbines, about the size of a refrigerator, with a stand-alone output of less than 1000kW. They evolved from car and truck turbochargers, aircraft auxiliary power units (APUs) and small jet engines.

High-velocity exhaust gases from the combustor spin the turbines used in microturbines. The basic principle of how a microturbine works is that the compressor and generator are mounted on the same power shaft as the turbine. Therefore, the compressor and generator also rotate together with the turbine. The generator spins at the same speed as the turbine and generates electricity. Electricity is first provided to power conditioning equipment and then supplied to the area where it is needed. The burner is supplied with gaseous fuel by a gas compressor. The compressor also supplies fresh compressed air to the combustion chamber through a recuperator. Here, the heat exchanger plays an important heat exchanger role. It absorbs heat from the hot gases from the turbine. It then provides this heat to the compressed air from the compressor. Therefore, the air supplied to the burner is hot and compressed. This helps improve the overall efficiency of the cycle.

Microturbine systems offer many advantages over reciprocating engine generators, such as higher power density (relative to footprint and weight), very low emissions, and few or only one moving part. Those designed with foil bearings and air cooling do not require oils, coolants or other hazardous substances. Microturbines also have the advantage of containing most of the waste heat in the relatively high-temperature exhaust, whereas a reciprocating engine's waste heat is distributed between its exhaust and cooling system.

The Global Microturbine Generators Market Size was estimated at USD 135.12 million in 2023 and is projected to reach USD 230.38 million by 2029, exhibiting a CAGR of 9.30% during the forecast period.
