## Abstracts

Military low-light-level night vision technology uses the principles of photoelectric conversion and electron multiplication to amplify weak natural nighttime light (such as starlight, moonlight, and airglow) by tens of thousands of times, generating images visible to the human eye. This technology facilitates covert observation, targeting, and reconnaissance missions. Its core component is the low-light-level image intensifier, which consists of a photocathode, a microchannel plate (MCP), and a phosphor screen. Image enhancement is achieved through the "photon ? electron ? multiplication ? photon" process. It does not require an active infrared light source and offers high concealment capabilities, but is significantly affected by ambient lighting conditions. Gross profit margins can reach 60%-70%. The upstream industry chain focuses on core materials and equipment: photocathode materials (such as gallium arsenide and polyalkali compounds) determine sensitivity and spectral response, MCP materials (high secondary emission coefficient glass) influence electron multiplication efficiency, and vacuum coating equipment and photolithography machines ensure manufacturing precision. The midstream focuses on device manufacturing and integration: Manufacturers focus on image intensifier R&D, facing challenges such as photocathode activation processes and MCP aspect ratio control. Integrators couple image intensifiers with CCD/CMOS sensors, optical lenses, and other components to create end products such as night vision devices and riflescopes. The downstream sector covers military, security, and industrial testing sectors.

The global Military Low-Light-Level Night Vision Technology market size was estimated at USD 269.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.90% during the forecast period.
