Abstracts

Mobile phase degassing refers to the process of removing dissolved gases, primarily oxygen and nitrogen, from the liquid solvents used as the mobile phase in high-performance liquid chromatography (HPLC) and ultra-high-performance liquid chromatography (UHPLC) systems, as these gases can form bubbles that interfere with pump performance, cause baseline noise, reduce detection sensitivity, and compromise the accuracy and reproducibility of analytical results. This is typically achieved through methods such as helium sparging, vacuum degassing, inline membrane-based degassing, or ultrasonic treatment, with modern systems often incorporating automated, continuous degassing units integrated directly into the chromatographic setup to maintain consistent solvent composition and system stability.

The global Mobile Phase Degassing market size was estimated at USD 220.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.75% during the forecast period.
