Abstracts

Ophthalmoscope is an instrument used for viewing the inside of the eye that consists of a concave mirror with a hole in the middle through which the physician examines the eye, and a light source that is reflected into the eye by the mirror. An indirect ophthalmoscope is a device that produces a reversed or inverted direct images with two to five times magnification. In comparing direct vs indirect ophthalmoscope, the indirect ophthalmoscope delivers a stronger source of light, greater opportunity for stereoscopic inspection of the eyeball interior, and a specifically designed objective lens. Indirect ophthalmoscopes have proven to be an exceptionally valuable device for the treatment and diagnosis of detachments, holes, and retinal tears. In order for the satisfactory use of an indirect ophthalmoscope, the patient's pupils must be completely dilated. Monocular indirect ophthalmoscopes offer a wider field of view and higher magnification levels than the traditional ophthalmoscope. As the name suggests, however, the monocular indirect ophthalmoscope only offers a single view of the eye's interior. For a physician to properly assess a patient's ocular condition and fundus, you should have the patient look in multiple directions.
