Report Overview

The Multi-Contrast Resolution Target is a test tool used to evaluate the contrast and resolution performance of an imaging system. It is usually a pattern plate or image with different gray levels and spatial frequencies, which is used to measure the performance of the imaging system under different contrast and spatial frequency conditions. Multi-contrast resolution targets typically contain a series of stripes, checks, or grid patterns with varying gray levels, from bright to dim or black to white, to produce images of varying contrast. At the same time, these patterns also have different spatial frequencies, from low to high frequencies, to simulate images with different levels of detail. Using a multi-contrast resolution target, the contrast and resolution performance of an imaging system can be evaluated by observing and analyzing the sharpness, contrast, and detail visibility of fringes, lattices, or grids in the image. This helps determine the capabilities of the imaging system, including the ability to discern detail and generate contrast. Multi-contrast resolution targets are widely used in image quality assessment, camera calibration, image processing algorithm development and comparison, etc. It can provide quantitative and qualitative indicators to help evaluate and optimize the performance of imaging systems, thereby improving the visual quality and recognizability of images.
