Abstracts

A multi-junction space solar cell is an advanced photovoltaic device specifically engineered for use in space applications, designed to efficiently convert solar radiation into electrical energy. These cells are composed of multiple layers, or junctions, of semiconductor materials, each optimized to absorb different wavelengths of the solar spectrum. By stacking these junctions, the cell can capture a broader range of photon energies, thereby significantly increasing its overall conversion efficiency compared to single-junction solar cells. Commonly used semiconductor materials in multi-junction cells include gallium arsenide (GaAs), indium phosphide (InP), and other compound semiconductors, which are carefully selected for their unique electronic properties and ability to work in tandem. In the harsh environment of space, where exposure to high levels of radiation and extreme temperature variations is a concern, multi-junction space solar cells are designed to be highly durable and reliable, ensuring a consistent power supply for satellites, space probes, and other space-based systems over extended periods of operation.

The global Multi-Junction Space Solar Cells market size was estimated at USD 293.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.30% during the forecast period.
