Abstracts

Navigational inertial systems are self-contained guidance technologies that use a combination of accelerometers and gyroscopes to continuously calculate the position, orientation, and velocity of a moving object without requiring external references. These systems operate by measuring linear acceleration and angular velocity, then integrating these measurements over time to derive motion parameters such as direction, speed, and precise location. Due to their autonomy from external signals like GPS, they are highly valued in applications where signal denial or interference is a concern, including military operations, underwater navigation, aviation, and space missions. The core components—inertial measurement units (IMUs) and inertial navigation systems (INS)—vary in accuracy and complexity based on sensor quality, with higher-end systems incorporating advanced error-correction mechanisms to minimize drift over time.

The global Navigational Inertial System market size was estimated at USD 532.18 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.75% during the forecast period.
