Abstracts

Non-raphitizable carbon refers to a class of carbon materials that cannot be converted into graphite even when subjected to high-temperature graphitization processes (typically above 2500°C), distinguishing them from graphitizable carbons which undergo structural ordering and crystallization under similar conditions; this property arises from their highly disordered, cross-linked molecular structure, often derived from precursor materials with high oxygen content or strong covalent bonding networks, such as certain resins, sugars, or chars, which inhibit the alignment of carbon layers necessary for graphite formation. These materials exhibit characteristics like high hardness, chemical inertness, and thermal stability, making them suitable for applications requiring robust, non-lubricating, and oxidation-resistant components, including seals, bearings, refractory linings, and specialized electrodes, where graphite's softness or lubricity would be undesirable.

The global Non Raphitizable Carbon market size was estimated at USD 3200.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.50% during the forecast period.
