Report Overview

A non-synchronous boost converter is a power converter used to convert low voltage DC power to high voltage DC power. It is a circuit that works asynchronously, consisting of a switching tube, an inductor, a diode and an output capacitor. The working principle of a non-synchronous boost converter is to control the flow of current by periodically turning the switching tube on and off. When the switch is turned off, the current in the inductor begins to increase, storing energy. When the switch is turned on, the current in the inductor begins to decrease, releasing energy. Through periodic switching operations, the current in the inductor generates a pulse voltage, which is filtered by the diode and output capacitor to obtain a stable high-voltage output.
