Abstracts

The fire-retardant performance of buildings and materials is categorized into three major groups: noncombustible, quasi-incombustible, and flame-retardant. Noncombustibility refers to the ability to withstand high temperatures for a certain period. It protects a building's interior structure by preventing flame spread for a specified duration, even under direct exposure to fire. Quasi-incombustibility has similar heat resistance to noncombustibility but doesn't meet the same duration criteria. Flame-retardant materials resist flames, limiting fire spread and ceasing combustion quickly in case of a fire. Noncombustible wood is a building material specially treated to be fire-resistant. It is increasingly used in construction sites and public facilities where fire resistance is essential. With the growing use of wood in various buildings, noncombustible wood is gaining significant attention. Due to its fire resistance, noncombustible wood finds diverse applications in construction, such as in roofing, exterior walls, ceilings, walls, and floors. Its high noncombustibility prevents rapid fire spread, enhancing a building's fire resistance performance. It is especially pertinent in hotels, hospitals, high-rise buildings, nursing homes, and daycare centers, where fire resistance is crucial. Selection of noncombustible wood should be based on the specific location and intended purpose.

The global Noncombustible Wood market size was estimated at USD 1080.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.40% during the forecast period.
