Abstracts

Ocean Carbon Removal refers to a series of technologies aimed at directly reducing global greenhouse gas concentrations by enhancing the ocean's ability to absorb and store atmospheric carbon dioxide through human intervention. Its core principle relies on the ocean's natural role as the largest carbon sink in the Earth system, achieving active carbon removal by accelerating or simulating ocean carbon pumping processes. Key technological pathways include: stimulating phytoplankton growth by adding iron ions and other nutrients to iron-deficient sea areas, using biopumps to transport organic carbon to the deep sea; creating artificial upwellings to raise deep-sea nutrients to the photosphere to increase primary productivity; alkalizing the ocean by introducing alkaline substances such as silicate minerals to enhance the buffering capacity of the seawater carbonate system and solidify more carbon dioxide; electrolyzing seawater to adjust its pH, promoting the dissolution of atmospheric carbon dioxide and its eventual precipitation as carbonates; and large-scale cultivation of kelp and other macroalgae, followed by their organized settling into the deep sea for long-term carbon sequestration. Most of these technologies are currently in the basic research and small-scale trial stage, and they all face key challenges such as ecological risk uncertainty, difficulty in monitoring and verification, high cost-effectiveness ratio, and lack of international governance framework. Their future large-scale application must be based on scientific assessment of their impact on marine ecosystems and global regulatory consensus. Globally, ocean carbon removal presents a pattern of "North America leading R&D, Europe focusing on remediation, and Asia-Pacific exploring applications." The United States leads in electrochemical carbon deposition and alkalization, leveraging its technological advantages; Europe focuses on ecological risk assessment and the development of international rules through its research network; and China has achieved initial applications of biological carbon pumps through the construction of large-scale algae farms. Currently, most technologies are in the pre-pilot stage, with costs

ranging from hundreds to thousands of US dollars per ton of carbon dioxide. Future development will depend on breakthroughs in three areas: the unification of international carbon measurement standards, the improvement of ocean governance conventions, and an exponential reduction in alkalization costs through material innovation. Large-scale demonstration is expected after 2035.

The global Ocean Carbon Removal market size was estimated at USD 798.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 13.50% during the forecast period.
