Abstracts

The oil-immersed iron core reactor is a type of electrical equipment that uses oil as a cooling medium. It is widely used in power transmission and distribution systems, industrial power grids, and special power application scenarios. It uses the inductance characteristics of the iron core and the coil to provide reactance to adjust the grid voltage, limit short-circuit current, or filter harmonics. Its design features and performance make it suitable for high-voltage and high-power applications. Reactance is generated through inductance, providing resistance to rapidly changing currents. When the current or voltage in the grid is abnormal, the reactor plays a role in protecting the equipment and stabilizing the operation of the grid. Oil as a cooling medium can effectively dissipate heat, ensuring that the equipment can operate stably for a long time under high load conditions.

The global Oil Immersed Iron Core Reactor market size was estimated at USD 867.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.60% during the forecast period.
