Abstracts

Human oocyte cryopreservation (egg freezing) is a procedure to preserve female eggs (oocytes). The eggs are extracted, frozen and stored. The purpose of the procedure is to give women the option of thawing, fertilizing and transplanting the eggs into the uterus as embryos to promote future pregnancy. Oocyte cryopreservation refers to the technology of cooling human oocytes and storing them in liquid nitrogen (generally stored in liquid nitrogen at -196°C), resuscitating (thawing) them when needed, and ensuring that the oocytes are alive and functioning normally. It is a derivative technology of assisted reproductive technology, mainly used to treat infertility and preserve female fertility. The driving factors of the oocyte cryopreservation market mainly include the following aspects: Technological progress The continuous improvement and maturity of oocyte cryopreservation technology has improved the recovery rate and survival rate of frozen oocytes, thereby increasing the clinical application prospects of this technology and driving the development of the market. Changes in fertility concepts The changes in modern women's fertility concepts and the intensification of the trend of late marriage and late childbearing have led more and more women to choose oocyte cryopreservation technology to maintain fertility and provide guarantees for future fertility plans. Growth in medical demand With the improvement of medical standards and people's attention to reproductive health, more and more medical institutions and patients have begun to pay attention to oocyte cryopreservation technology, which has promoted the rapid development of the market. Policy support The support policies of some countries and regions for assisted reproductive technology, as well as the improvement of relevant laws and regulations, have provided a good policy environment for the development of oocyte cryopreservation technology. Unlike sperm, oocytes are larger and contain a lot of water, which makes it easier to form ice crystals that may damage the eggs during the freezing process. In addition, egg extraction is not easy and the number is scarce, so the selection of protective agents during the freezing

process is also more demanding. These factors have made egg freezing one of the difficulties in freezing technology. However, with the continuous advancement of technology, the success rate of oocyte cryopreservation has been significantly improved. International clinical trials have proven that frozen eggs can be stored for at least ten years, and they still have the ability to conceive after thawing, can form healthy embryos, and can normally conceive babies. This has led more and more women to choose to preserve their future reproductive ability through oocyte cryopreservation technology, that is, to buy a "fertility insurance". In general, oocyte cryopreservation technology provides an effective option for women who want to preserve their fertility, and also provides new possibilities for the development of assisted reproductive technology.

The global Oocyte Cryopreservation Service market size was estimated at USD 91.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 15.00% during the forecast period.
