Abstracts

The optical fiber photometry system is a highly sensitive, highly specific, and highly real-time neuroscience research tool. Based on optical technology, the light source emits excitation light of a specific wavelength band, which is reflected by a dichroic mirror and then coupled to one or more multimode optical fibers by the objective lens. The end of the optical fiber transmits the excitation light to a specific brain area of ??the test animal (such as a mouse) to excite neurons marked by GCaMP calcium-sensitive fluorescent protein or other sensitive fluorescent probes. The intensity of fluorescent protein in neurons is regulated by calcium ion concentration or other neurotransmitters, and its fluorescence changes are transmitted back to the detection optical path through the same optical fiber, collected in the form of images by detectors such as CMOS, and converted into voltage signals for display and recording. The optical fiber photometry system has high sensitivity, little damage, real-time performance, and specificity. It is widely used in many aspects of neuroscience, including animal behavior and neuroscience research, exploration of the molecular mechanism of neural circuits, and detection of changes in neurotransmitter signals.

The global Optical Fiber Photometry System market size was estimated at USD 741.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.60% during the forecast period.
