Report Overview

Parallel backlight LED driver is a circuit used to control multiple LED strings, which can ensure that the voltage of each string is equal, so as to achieve uniform backlighting. Parallel backlight LED drivers are usually used for backlighting LCD screens, such as TVs, tablets, laptops, etc. Parallel backlight LED drive has the following advantages: It can improve system stability and reliability, and avoid the failure of a single LED string from affecting other strings. The drive current can be reduced, reducing power consumption and heat dissipation. Can simplify circuit design, reduce component count and cost. The principle of parallel backlight LED driving is to use a constant voltage source or a constant current source to provide a fixed reference voltage or current, and distribute it to each LED string through components such as resistors or inductors. This can ensure that the voltage or current of each LED string is consistent with the reference value, and will not be affected by factors such as LED forward voltage drop, temperature, and aging. There are many ways to realize parallel backlight LED driving, for example: using a constant voltage source as a reference voltage and distributing the current through resistors. Use a constant current source as the reference current and distribute the voltage through the inductor. The integrated circuit chip is used as a dedicated backlight LED driver, and the constant voltage or constant current control function of multiple channels is integrated inside.

The global Parallel Backlight Led Driver market size was estimated at USD 385.42 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.85% during the forecast period.
