Abstracts

A Passive In-Building Cellular Enhancement System (also known as Passive DAS, or Passive Distributed Antenna System) is a type of wireless communication solution used to improve mobile network coverage inside buildings. It works by distributing signals from external cellular towers to the interior of a building without the need for active amplification of the signals. In a passive system, the cellular signals are captured from the external environment, typically by an external antenna (or donor antenna), and then routed through coaxial cables to a network of indoor antennas. These indoor antennas rebroadcast the signal throughout the building, improving cellular connectivity in areas where the external signal may be weak or non-existent.

The global Passive In-Building Cellular Enhancement System market size was estimated at USD 877.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.90% during the forecast period.
