Abstracts

Pcsk9 targeted therapy refers to a class of biologic drugs designed to inhibit proprotein convertase subtilisin/kexin type 9 (Pcsk9), a protein that regulates the number of low-density lipoprotein (LDL) receptors on the surface of liver cells. By blocking Pcsk9, these therapies increase the availability of LDL receptors, enhancing the liver?s ability to remove LDL cholesterol from the bloodstream, thereby significantly reducing circulating LDL-C levels. Administered via subcutaneous injection, Pcsk9 inhibitors such as alirocumab and evolocumab are used primarily for patients with familial hypercholesterolemia or clinical atherosclerotic cardiovascular disease who require additional LDL-C lowering despite maximally tolerated statin therapy. Their mechanism offers a targeted, non-statin approach to lipid management, with effects that are both potent and sustained, making them a critical advancement in the treatment of refractory hypercholesterolemia and cardiovascular risk reduction.

The global Pcsk9 Targeted Therapy market size was estimated at USD 7500.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 8.50% during the forecast period.
