Abstracts

PEM (Proton Exchange Membrane) hydrogen production catalysts are materials used in PEM water electrolyzers to accelerate the electrochemical reactions that split water into hydrogen and oxygen. These catalysts are typically composed of precious metals, primarily platinum (Pt) at the cathode (hydrogen evolution reaction, HER) and iridium (Ir) or ruthenium (Ru) oxides at the anode (oxygen evolution reaction, OER). They facilitate the transfer of electrons and protons, reducing the overpotential required for the electrolysis process and improving its efficiency. The industry trend for PEM hydrogen production catalysts is driven by the increasing demand for high-efficiency, compact, and dynamic hydrogen production systems. Several key trends are shaping this field:

- Reducing iridium loading at the anode:** Iridium is a scarce and expensive metal, making it a major cost driver for PEM electrolyzers. A significant research focus is on reducing the iridium loading at the anode while maintaining or improving performance. Strategies include developing Ir alloys, core-shell structures with Ir on the surface, and novel support materials that enhance Ir utilization.
- Developing non-precious metal OER catalysts:** Extensive research is dedicated to developing non-precious metal catalysts for the OER, such as transition metal oxides, perovskites, and other materials. These materials offer the potential for significant cost reduction but often face challenges in terms of activity, stability, and corrosion resistance in the acidic PEM environment.
- Improving platinum utilization at the cathode:** While platinum is more abundant than iridium, improving its utilization at the cathode is still important for cost reduction and performance enhancement. This involves optimizing catalyst particle size, morphology, and distribution on the electrode support.
- Enhancing catalyst durability and stability:** The acidic environment and high operating potentials in PEM electrolyzers can lead to catalyst degradation. Therefore, improving catalyst durability and stability is crucial for long-term performance. This involves developing protective coatings, stable support materials, and strategies to mitigate corrosion and catalyst

dissolution. Developing advanced electrode structures: The performance of PEM catalysts is also influenced by the electrode structure. Researchers are exploring advanced electrode structures, such as porous transport layers (PTLs) with optimized pore size distribution and conductivity, to improve mass transport and catalyst utilization.

The global PEM Hydrogen Production Catalyst market size was estimated at USD 120.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.80% during the forecast period.
