Report Overview

The phase-shifting mask is widely used in the semiconductor chip manufacturing process to improve the resolution of the chip and the contrast of the pattern by introducing different phase shifts on the mask. The PSM works by creating transparent or opaque regions with different phases on the mask. When light passes through the mask, the light waves of different phases interfere, resulting in high-contrast and sharp patterns. Phase shifting can be achieved by changing the optical properties of the mask material or introducing special diffraction structures during the photolithography process.
