Abstracts

Photochemical etchants, also known as photoresist developers or etching chemicals, are specialized chemical solutions used in the microfabrication and printed circuit board (PCB) industries to selectively remove material from substrates through a photolithographic process. These etchants function by reacting with exposed areas of a substrate—typically metals like copper, aluminum, or stainless steel—that have been patterned using a light-sensitive photoresist and UV exposure, allowing for high-precision, intricate, and repeatable etching of fine features such as circuit traces, meshes, and microfluidic channels. The composition of photochemical etchants varies based on the material being etched and may include acidic formulations (e.g., ferric chloride for copper), alkaline solutions, or more specialized chemistries tailored to specific alloys or applications requiring minimal undercut and high etch factor ratios.

The global Photochemical Etchants market size was estimated at USD 182.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 5.75% during the forecast period.
