## Abstracts

The physical cross-linking method is to irradiate polyethylene with high-energy particle rays (such as  $\gamma$  rays) generated by an electron accelerator, so that the polyethylene becomes a cross-linked polyethylene with a bonded chain state. The polyethylene molecules with bonded chains are combined with each other to form a three-dimensional spatial network structure. Therefore, physical cross-linking is also called irradiation cross-linking. The advantages of physical cross-linking are uniform cross-linking, fewer pinholes and bubbles, no scorching (local over-cross-linking), and low energy consumption. It belongs to cold cross-linking. Since physical cross-linking must have special additional equipment (electron accelerators and closed radiation-proof sites, etc.), the radiation energy is proportional to the thickness of the insulation layer. Therefore, the physical cross-linking method is mostly used to make thin films. The insulation layer of cables (especially high-voltage cables) is thicker, and physical cross-linking is rarely used. Most of them use chemical cross-linking.

The global Physically Cross Linked Polyethylene market size was estimated at USD 1485.73 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.40% during the forecast period.
