Report Overview:

Plasma sputtering coater is a physical vapor deposition process used to apply very thin functional coatings on substrates. The process begins by charging the sputtering cathode, which then creates a plasma that ejects material from the target surface. The target material is glued or clamped to the cathode and magnets are used to ensure stable and uniform corrosion of the material. At the molecular level, the target material is directed towards the substrate through a momentum transfer process. High-energy targets strike the substrate and are driven to the substrate surface, forming very strong bonds at the atomic level. This material is now a permanent part of the substrate rather than an applied coating or plating on the surface. This paper mainly studies the plasma coating sputtering apparatus.

The Global Plasma Sputtering Coater Market Size was estimated at USD 487.01 million in 2023 and is projected to reach USD 1024.75 million by 2029, exhibiting a CAGR of 13.20% during the forecast period.
