Report Overview

Track-etched membranes have well-defined pore structures and pore size distributions. The pore size and the density of track-etched membranes is independently controlled during the production process. The main manufacturing stage of track-etched membranes is the ion irradiation of the polymer film. During this step, heavy ions are able to penetrate the polymer film, resulting in ionization and excitation of electrons. In the second step of production, the remaining polymer chains are etched using appropriate chemicals to remove small-sized particles through diffusion. The major features of track-etched membranes are well-defined cylindrical geometry of pores, low protein binding, and smooth surface for collection of particles for observation under microscopes.

Track-etched membranes are used for the purification of drugs and vaccines, fluid clarification, microscopy, bioassays, environmental analysis, and in bacterial quality control of food and water. These membranes are also used in clean rooms, drinking water purification, and in analytical systems. These membranes have a defined pore size, high flow rate, and high thermal and chemical stability. The major advantages of track-etched membranes are no contamination of the sample and smooth surface for enhanced visibility of particles.
