Abstracts

A polymerisation inhibitor is a chemical additive specifically designed to prevent or significantly delay the uncontrolled or premature polymerisation of monomers during their production, storage, handling, or transportation. These inhibitors function by reacting with free radicals or terminating chain reactions, thereby preserving monomer stability and ensuring safety by mitigating risks associated with exothermic reactions, such as thermal runaway, equipment fouling, and hazardous material build-up. Commonly used inhibitors include compounds like hydroquinone, methylhydroquinone, tert-butylcatechol, and phenothiazine, which are selected based on factors such as monomer type, required inhibition period, temperature conditions, and compatibility with downstream processes. Their application is critical in industries dealing with reactive monomers?such as styrene, acrylic acid, vinyl acetate, and butadiene?where maintaining product quality, operational safety, and process efficiency is paramount.

The global Polymerisation Inhibitor market size was estimated at USD 285.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 5.50% during the forecast period.
