Report Overview

Positive allosteric modulators (PAMs) are a class of pharmacological agents that enhance the activity of a target receptor or protein by binding to an allosteric site distinct from the orthosteric (active) site, thereby amplifying the effects of endogenous ligands without directly activating the receptor themselves. Unlike traditional agonists, PAMs offer greater selectivity and reduced risk of overstimulation, making them particularly valuable in therapeutic areas such as neurology (e.g., targeting GABA or glutamate receptors for epilepsy or cognitive disorders) and psychiatry (e.g., modulating dopamine or serotonin receptors for schizophrenia or depression). Their ability to fine-tune receptor activity while preserving physiological signaling patterns has positioned PAMs as a promising alternative in drug development, especially for conditions where conventional orthosteric drugs face limitations due to side effects or tolerance issues. The market for PAMs is driven by increasing research into central nervous system (CNS) disorders, a growing pipeline of preclinical and clinical candidates, and collaborations between pharmaceutical companies and academic institutions to explore novel mechanisms of action. However, challenges such as complex structure-activity relationships, potential off-target effects, and regulatory hurdles in demonstrating efficacy and safety in clinical trials may impact commercialization timelines. Despite these obstacles, the demand for PAMs is expected to rise, supported by advancements in structural biology, high-throughput screening, and a shift toward precision medicine in treating complex diseases.
