Report Overview:

PET scanner is a type of nuclear medicine imaging. The scan uses a special dye that has radioactive tracers.

Positron-emission tomography (PET) is a nuclear medicine functional imaging technique that is used to observe metabolic processes in the body. The system detects pairs of gamma rays emitted indirectly by a positron-emitting radionuclide (tracer), which is introduced into the body on a biologically active molecule. Three-dimensional images of tracer concentration within the body are then constructed by computer analysis. In modern PET-CT scanners, three-dimensional imaging is often accomplished with the aid of a CT X-ray scan performed on the patient during the same session, in the same machine.

The Global Positron Emission Tomography (PET) Market Size was estimated at USD 792.23 million in 2023 and is projected to reach USD 962.62 million by 2029, exhibiting a CAGR of 3.30% during the forecast period.
