Abstracts

Powder-based intraoral scanners are dental devices used to capture digital impressions of a patient's teeth and oral tissues, requiring the application of a fine layer of contrast powder on the surfaces being scanned. The powder, typically made from titanium dioxide, is used to reduce reflective surfaces and improve the accuracy and quality of the digital scan by providing a uniform surface. The scanner then captures images of the powdered area, which are processed into a detailed 3D digital model. These scanners were common in earlier models but have largely been replaced by more advanced powder-free systems, which improve patient comfort and workflow efficiency.

The global Powder-based Intraoral Scanners market size was estimated at USD 52.1 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.10% during the forecast period.
