Abstracts

Proteasome inhibitor drugs represent a specialized class of therapeutics that function by selectively inhibiting the proteasome, a large protein complex responsible for degrading damaged or unneeded proteins within cells; by blocking this degradation pathway, these drugs induce an accumulation of misfolded proteins and trigger apoptosis, or programmed cell death, particularly in rapidly dividing cells such as cancer cells, making them especially effective in the treatment of hematologic malignancies. These targeted agents are primarily utilized in oncology, with key applications including multiple myeloma and mantle cell lymphoma, where they have become cornerstone treatments either as monotherapies or in combination regimens, and they are characterized by their mechanism of action which disrupts intracellular protein homeostasis, leading to endoplasmic reticulum stress and ultimately cell cycle arrest and death in malignant cells. The development and refinement of proteasome inhibitors continue to focus on enhancing specificity, reducing off-target effects, and overcoming drug resistance, with both intravenous and oral formulations now available, expanding their utility and accessibility in clinical practice.

The global Proteasome Inhibitor Drug market size was estimated at USD 2615.75 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.40% during the forecast period.
