Report Overview

A proximal femoral intramedullary nail is a medical device used in orthopedic surgery to treat fractures of the proximal femur, which is the upper part of the thigh bone. It is inserted into the medullary cavity (the hollow center) of the femur to stabilize and align the fractured bone fragments. The nail is typically made of metal and has a long, slender shape that allows it to be inserted through a small incision. It provides internal fixation, meaning it holds the bone fragments together to promote healing and restore normal function. The nail is secured with screws or locking bolts at the proximal (near the hip) and distal (near the knee) ends to ensure stability. This surgical technique is commonly used in cases of hip fractures, particularly in elderly patients.
