Abstracts

PVD and ALD coatings for chamber components are typically based on yttrium or aluminum oxides or may be made from aluminum oxynitride (AlON). The exact chemistry and coating thickness must be tailored to the application. The use of temperature in the chamber, processing time, and gases vary considerably depending on the device specifications, and these variables are used to select the right combination of coatings for their desired coating performance. Custom precision-engineered coatings provide the optimal balance between cost and performance. Deposition chambers contain various parts and components that either contact the device wafer directly or are exposed to process chemicals that subsequently reach the wafer. As such, material selection is critical. The corrosive chemicals used in plasma-etch chambers attack the tool component surfaces and degrade coatings. Longer exposure to hotter plasmas, which is common for 3D device processing, accelerates degradation. Particles shed from the corroded surfaces then deposit on the wafers, potentially causing device failure. Components protected with yttrium oxide deposited by plasma spray-coating or made from anodized aluminum have long been the industry norm. Although such solutions have worked for many years, the nano-scale features of advanced process nodes demand an increased level of cleanliness for every part in the system. Conventionally coated components are not rugged enough to withstand the aggressive environments inside etch and deposition chambers without impacting device yield. Plasma spray coatings are relatively rough and porous, while anodized coatings exhibit in-situ cracking that makes them degrade too readily. The complex shapes of parts inside deposition chambers also pose a challenge for spray coating, which works best when coating planar surfaces. Precision engineered, specialized coatings borrow vacuum thin film technologies associated with semiconductor wafer processing to produce coated components that can better resist the corrosion and oxidation that

degrade conventional coatings. Two options are available: physical vapor deposition (PVD) and atomic layer deposition (ALD). Every precision engineered coating must exhibit a minimum level of wear and corrosion resistance in the presence of corrosive plasma/chemistry and adhere fully to the underlying substrate to create a uniformly coated surface. The geometry and material of the part being coated, the type of chamber, and the processing conditions further dictate the optimal coating chemistry and method. Global key players of PVD and ALD Coating for Chamber Components include Entegris, KoMiCo, Inficon, etc. The top three players hold a share about 50%. Asia-Pacific is the largest market, and has a share about 58%, followed by North America and Europe with share 35% and 7%, separately. In terms of Coating Method, PVD Coating Method is the largest segment, accounting for a share of 65%. In terms of application, Etching Tools is the largest field with a share about 86 percent.

The global PVD and ALD Coating for Chamber Components market size was estimated at USD 53.7 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 9.20% during the forecast period.
