Report Overview

Binder is one of the important components of lithium ion battery pole piece. It is a polymer compound that adheres the active material and conductive agent in the electrode piece to the electrode current collector. It can enhance the contact between the active material, the conductive agent and the current collector. The performance and the role of stabilizing the structure of the pole piece are additional materials with high technical content in lithium-ion battery materials. Studies have shown that although the amount of binder used in the electrode sheet is small, the performance of the binder directly affects the capacity, life and safety of the battery. PVDF is currently the most commonly used oily binder in the lithium-ion battery industry. It is a non-polar chain-packed polymer binder. Its outstanding features are strong oxidation-reduction resistance, good thermal stability, and easy to disperse, but it needs to use N-methylpyrrolidone (NMP) as a solvent. The volatilization temperature is high, there is a certain degree of environmental pollution, and the price is expensive. Obvious shortcomings include relatively high Young's modulus, between 1-4 GPa, the flexibility of the pole piece is not good enough; after PVDF absorbs water, the molecular weight decreases and the viscosity becomes worse, so the humidity requirements of the environment are relatively high; for ions and electrons Insulation, a certain degree of swelling in the electrolyte, and exothermic reaction with metallic lithium and Li_xC_6 at higher temperatures, which is detrimental to the safety of the battery.

The global PVDF Binders for Batteries market size was estimated at USD 350 million in 2023 and is projected to reach USD 460.68 million by 2032, exhibiting a CAGR of 3.10% during the forecast period.
