Abstracts

A quartz monitor crystal is a crucial component of a quartz crystal based measurement and control system. The crystal enables precise and repeatable thin film depositions for a wide variety of high end uses. Quartz materials will develop an electrical charge like a battery, when pressed or squeezed. This property is called the piezoelectric effect ('pea-a-zo'). Conversely, if a battery were connected to a crystal, the crystal would change shape by stretching or compressing. If the battery were then turned on and off quickly in rapid succession, the crystal would vibrate. Depositing a thin coating on the crystal's surface will slow down the vibration of a quartz crystal. The crystal vibrates at approximately 6 million times per second (or 6 Megahertz), given a real time measurement of the thickness of coating being deposited on the crystal or any object in its vicinity. As the coating deposits on the crystal, the monitor counts the change in the number of vibrations per second and calculates the thickness of the coating from the data it receives.
