Abstracts

A radiographic intensifying screen is a device used in X-ray imaging systems to enhance the brightness or intensity of X-ray images. Typically made from fluorescent materials such as tungsten, tellurium, or barium sulfate, these screens convert X-rays passing through them into visible light, thereby reducing the X-ray dose required for image capture and improving the quality of the image. Radiographic intensifying screens are commonly used in medical radiology, industrial non-destructive testing, and other fields to enhance image clarity and reduce radiation exposure to patients or samples.

The global Radiographic Intensifying Screen market size was estimated at USD 546.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.10% during the forecast period.
