Abstracts

Radionuclide-conjugated drugs (RCDs) are a novel type of therapeutic drug combining precise targeting and potent killing. Their structure is similar to antibody-drug conjugates (ADCs), but the toxic payload is replaced by a radionuclide. They mainly consist of four parts: a targeting ligand responsible for specific tumor recognition, a linker arm, a chelating agent to stabilize the bound radionuclide, and the radionuclide itself. After entering the body, the ligand guides the radionuclide to precisely accumulate at the tumor site. The radiation released during radionuclide decay destroys tumor cell DNA from within, achieving highly effective treatment. If imaging radionuclides are used, they can be used for tumor localization and diagnosis.The market prospects for RCDs are extremely broad, leading to the rapid rise of the radiopharmaceutical industry. The core drivers of future growth lie in technological iteration and application expansion: therapeutic radionuclides are upgrading from current ?-radionuclides to next-generation ?-radionuclides with stronger and more precise killing power; indications are expanding from prostate cancer and neuroendocrine tumors to more solid tumors and even non-tumor fields. With policy support and capital investment, pharmaceutical companies from various countries are vying to break through bottlenecks in the industrial chain, such as isotope supply, production and distribution. The unique advantages of integrated diagnosis and treatment will make RDC an important pillar for precision cancer treatment.

The global Radionuclide Drug Conjugate(RDC) market size was estimated at USD 9852.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 9.60% during the forecast period.
