Abstracts

A recirculating liquid chiller is a self-contained, closed-loop cooling system designed to maintain precise temperature control in industrial and laboratory applications by continuously circulating a coolant—typically water or a water-glycol mixture—through an external process or equipment, extracting heat, and dissipating it via an integrated refrigeration cycle. These systems are distinguished by their ability to provide stable, consistent cooling without consuming large volumes of water, as the coolant is recirculated rather than discharged, making them both efficient and environmentally favorable compared to once-through cooling methods. Key components include a compressor, condenser, evaporator, pump, and temperature controller, allowing for adjustable setpoints and adaptability to varying thermal loads in processes such as laser cooling, chemical reactor temperature regulation, medical imaging equipment, and plastic injection molding.

The global Recirculating Liquid Chiller market size was estimated at USD 7250.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 5.80% during the forecast period.
